

How to view base station power supply load current

Overview

What is a base load power station?

The total load on a power station consists of two parts viz., base load and peak load. In order to achieve overall economy, the best method to meet load is to interconnect two different power stations. The more efficient plant is used to supply the base load and is known as base load power station.

What are the characteristics of a power supply?

The quality of a power supply depends on its load regulation, line regulation, and output resistance. In this section, we will look at these characteristics because they are often used on data sheets to specify power supplies. Figure 1 shows a bridge rectifier with a capacitor-input filter. Changing the load resistance will change the load voltage.

What is the difference between base load and peak load power station?

The more efficient plant is used to supply the base load and is known as base load power station. The less efficient plant is used to supply the peak loads and is known as peak load power station. There is no hard and fast rule for selection of base load and peak load stations as it would depend upon the particular situation.

What if a power supply has a low output resistance?

This means that the load voltage varies less than 0.1 percent when the line voltage varies from 105 to 125 Vrms. The Thevenin or output resistance of a power supply determines the load regulation. If a power supply has a low output resistance, its load regulation will also be low. Here is one way to calculate the output resistance:.

What is a full load if a power supply is rated?

If it is supplying the rated current (same as maximum current) at the rated voltage, then the load that is connected is the full load. There is no set value

for a full load because each power supply is rated differently. The more important value that many people should be concerned with is the minimum load requirement.

How do you calculate the minimum load of a power supply?

Use the formula for power: Power = Voltage x Current, or $P = VI$. If for any reason you only have the current and power ratings of your power supply, you can use $P = I^2 R$, which can be changed to $R = P/I^2$. As you can see, calculating the minimum required load of your power supply is a very simple process.
